Hard Reload

Metric	Value
Requests	736
Data transferred	9.9 MB
Total resource size	36.6 MB
Finish time	7.13 s
DOMContentLoaded	2.52 s

Compression Reduction

- **Transferred:** 9.9 MB
- **Total resources:** 36.6 MB

This means approximately **26.7 MB** of data was saved through compression, a reduction of about **73%**.

Soft Reload

Metric	Value
Requests	679
Data transferred	1.0 MB
Total resource size	36.4 MB
Finish time	6.60 s
DOMContentLoaded	2.97 s
Load	6.21 s

Reduction Due to Caching

- Hard reload transferred: **9.9 MB**
- Soft reload transferred: **1.0 MB**

The browser downloaded approximately **8.9 MB less data** on the second visit, which is roughly a **90% reduction** due to caching.

Resource Breakdown

Resource Type	Transferred	Resource Size
JavaScript	89.1 kB	3.42 MB
Images	640 kB	21.9 MB
CSS	0.0 kB	2.13 MB

The transferred sizes are much smaller than the total resource sizes:

- JavaScript: **89.1 kB transferred vs 3.42 MB resources**
- Images: **640 kB transferred vs 21.9 MB resources**
- CSS: **0 kB transferred vs 2.13 MB resources** (served entirely from cache)

This indicates that compression and browser caching are both being used effectively.

Findings

Finding 1: Very Large Number of Requests

Most likely cause:

The homepage loads many news articles, advertisements, analytics scripts, videos, fonts, and other third-party resources.

How does this affect users?

Making **736 network requests** increases the amount of work the browser has to perform before

the page is fully loaded. This can slow down loading, especially on slower devices and networks.

Affected metrics:

- Finish Time
- Performance
- Largest Contentful Paint (LCP)

Likely solution:

Reduce unnecessary requests by combining files where possible, removing unused third-party scripts, and lazy-loading resources that are not immediately needed.

Finding 2: Images Make Up Most of the Page Size

Most likely cause:

The homepage contains many high-resolution news photographs.

How does this affect users?

Images account for approximately **22 MB** of the **36.6 MB** total page size, meaning they are responsible for most of the download. Large images increase loading times and consume more mobile data.

Affected metrics:

- Largest Contentful Paint (LCP)
- Speed Index
- Finish Time

Likely solution:

Use responsive images, compress images further, and serve modern formats such as WebP or AVIF where possible.

Finding 3: JavaScript Is Still Significant

Most likely cause:

The website loads numerous JavaScript files for advertisements, analytics, videos, comments, and interactive features.

How does this affect users?

Although JavaScript is much smaller than images, over **3.4 MB** of scripts still need to be processed, increasing CPU usage and slowing page interaction.

Affected metrics:

- Total Blocking Time (TBT)
- Interaction to Next Paint (INP)
- Performance Score

Likely solution:

Remove unused JavaScript, split large bundles into smaller files, and defer scripts that are not required during the initial page load.

Finding 4: Browser Caching Works Very Well

Most likely cause:

Static resources such as JavaScript, CSS, images, and fonts are cached by the browser after the first visit.

How does this affect users?

The amount of downloaded data drops from **9.9 MB** to **1.0 MB** on a normal refresh, making repeat visits much faster and reducing bandwidth usage.

Affected metrics:

- Data Transferred
- Finish Time
- Overall Performance

Likely solution:

Continue using long cache lifetimes for static resources and ensure new versions are delivered using cache-busting filenames when files change.
